

bisik.

bisik.

You whisper quotes. The market hears nothing.

A confidential multi-dealer RFQ desk for OTC block trades —
native on Canton.

Build on Canton Hackathon · Private DeFi & Capital Markets · team “Diam” (named
after our first build in the series below)

THE PROBLEM

You can't trade size in the open.

- Post a \$4M block on a public venue → the order and the competing bids leak.
- Front-running, market impact, leaked alpha the moment it hits the mempool.
- Today's fix: OTC desks & chat rooms — trust a middleman, no clean audit trail.
- \$30B+/month still trades this way.

WHAT BISIK IS

A sealed-bid RFQ desk where the guarantees are code, not a middleman.

- Buyer requests quotes from a **chosen dealer panel** — the market never sees the RFQ.
- Each dealer's quote is **sealed** — rival dealers never receive it.
- Cheapest ask wins, paid the **second price** (Vickrey) — atomic delivery-versus-payment.
- A regulator sees the executed trade — and **only** that — yet best execution stays **provable** via selective disclosure.

Confidential pre-trade, provable & auditable post-trade.

HOW IT WORKS

RFQ	buyer → invited dealers · no price on it
↓	
SubmitQuote	dealer locks the asset into escrow + seals a Quote (signatory: dealer + buyer · NO other observers)
↓	
Award	cheapest ask wins, paid the 2nd price · atomic DvP
↓	
TradeReport	cash → dealer + asset → buyer, both legs or neither regulator sees the settled trade – post-trade only

*Privacy = Canton sub-transaction privacy. Pricing = the Vickrey rule computed in the **Award** choice. Settlement = atomic DvP.*

THE INSTITUTIONAL PAYOFF

Provable best execution — with no public order book.

- A public exchange audits best execution against a **visible order book**. Bisik has none — pre-trade stays confidential.
- Yet the regulator still **proves** it: either side can **selectively disclose** a sealed ask to the regulator on demand — never to rivals.
- The desk confirms the winner quoted the lowest ask and the buyer paid no worse than any competitor.
- **Live on Devnet: 10 green attestations** across all three rails — Vickrey, direct OTC, partial fill.

Confidential pre-trade, provable post-trade.

The regulator’s view: executed price checked against the sealed asks the counterparties disclosed to it.

WHY CANTON — THE DIFFERENTIATOR

I built this exact desk four times before.

Build	Chain	Privacy machinery I had to write
Diam	iExec Nox	TEE confidential compute
Segel	Stellar	two Groth16 ZK circuits, hand-rolled Poseidon
Sealed Pair	Sui	Walrus commitments + Seal encryption
Samar	Zama fhEVM	fully-homomorphic encryption
Bisik	Canton	none — it's the ledger's data model

“Rivals can’t see the quote” is `signatory / observer` . ~40 lines of Daml replace thousands of lines of cryptography.

REAL-WORLD FIT

This is how OTC actually works.

- Multi-dealer RFQ is the Tradeweb / Bloomberg institutional workflow.
- Tradeweb is a Canton Super Validator — the workflow, native on the network they help run.
- Privacy guaranteed by the protocol; a regulator-observable audit trail.
- Maps directly to the track: “OTC trading workflows”, institutional relevance.

TECHNICAL EXECUTION

Built, tested, and live.

- Clean two-package Daml — the deployable model DAR carries no test/script bloat.
- Escrow-backed atomic DvP; the reverse-Vickrey clearing is computed on-ledger in the `Award` choice.
- 22 Daml behavioural scripts (privacy assertions, Vickrey 1/2/3, issuer-binding, one-quote-per-dealer, partial-fill math, symmetric disclosure) **plus three Playwright suites** that click every choice on the real desk end-to-end.
- Web desk over the JSON Ledger API — every model choice is drivable; award, disclosure, and best-execution flows verified end-to-end.
- **Agentic** — an MCP server (an agent verifies Canton's privacy itself) + an autonomous market-maker that quotes RFQs blind. Private DeFi × agentic commerce.
- **Deployed live on Canton Devnet** (5N validator) — dealers blind pre-trade, the regulator's post-trade audit populated, all proven on-ledger.

HONEST SCOPE · ROADMAP

Shipped, and what's next.

- **Shipped:** three settlement rails — competitive Vickrey, direct bilateral OTC, and **partial fills on both**; one-quote-per-dealer enforced on-ledger; **provable best execution** across all three.
- **Shipped:** **multi-instrument baskets** (atomic multi-leg DvP) and an **SSE push stream** so the desk updates the instant the ledger moves.
- **Shipped:** a CIP-0056-aligned **Token** interface — the plug for the full token standard (TransferInstruction / Allocation registries) next.
- **Ahead:** a trusted auctioneer to force the true second price even against a self-interested buyer. MPC would do it too — but that re-introduces the very cryptography Canton lets us skip.

bisik.

*The confidential OTC desk that finally didn't need a cryptography stack —
because Canton already is one.*
